Study the Effect of Dry Rose Petals (*Rosa damascena*) Powder on Blood Lipids and Glucose in Experimental Rats

Mohammed M. El-Sayed, Sherif S. Rageb, Omnia S. Mohammed
Department of Nutrition and Food Science, Faculty of Home Economics, Menoufia University, Shebin El-Kom, Egypt

Abstract:
This study was conducted to investigate the effect of rose petals (*Rosa damascena*) powder (RPP) on blood lipids and glucose in experimental rats. Fifty-Four adult male albino rats weighting 150±10g, were used, and divided into three main groups. First group (5 rats) fed on basal diet as control (-), Second group was induced diabetes by aloxan (150 mg/kg), third group was induced hyperlipidemia by fed rats on diet containing high lipids (basal diet + 20% animal fat sheep's tail) for three consecutive weeks. Diabetic and hyperlipidmic rats groups divided into four sub groups, rats per each two of them were diabetic and hyperlipidmic control positive. While the other groups fed a basal diet after replacing 1, 2.5 and 5% RPP and feeding continued for 30 days. After the treatment, body weight, feed intake (FI), (FER) and blood samples were measured and serum glucose, triglyceride, total cholesterol, LDL-C, AST, ALT and ALP levels were determined, while HDL-C and VLDL-C were calculated and histopathological structure of liver has been evaluated. The obtained results revealed that feeding on RPP caused significant (P ≤ 0.05) improvements in weight gain, FI, (FER), HDL-C, but with significant (P ≤ 0.05) decreases in the rest of the parameters as compared with control (+ve) group. Histopathological investigations confirmed the biochemical changes in rats serum. It could be concluded that rosa petals powder was effective in protecting against diabetic and hyperlipidmic rats not only decreased the level of serum glucose but also has beneficial effect on serum lipids and liver functions. Therefore, we recommended the RPP tested plant by a moderate amount (5%) to be included in our daily drinks and diets.

**Key words**: Diabetic rats, hyperlipidimic rats, rosa petals, serum lipids, liver functions.
Introduction

Diabetes mellitus is a group of metabolic diseases characterized by chronic hyperglycemia resulting from defects in insulin secretion, insulin action, or both. Metabolic abnormalities in carbohydrates, lipids, and proteins resulted from the importance of insulin as an anabolic hormone. Low levels of insulin to achieve adequate response and/or insulin resistance of target tissues, mainly skeletal muscles, adipose tissue, and to a lesser extent, liver, at the level of insulin receptors, signal transduction system, and/or effector enzymes or genes are responsible for these metabolic abnormalities (Craig et al., 2009).

Hyperlipidemia is common in the worldwide population, and is considered as a highly modifiable risk factor for cardiovascular disease such as coronary heart disease and peripheral artery diseases. Elevated blood lipid levels, especially increased serum low-density lipoprotein (LDL) level, can accelerate atherosclerosis. Therefore, reducing high lipid levels has been regarded to be an important approach to prevent or slow the progression of atherosclerosis (Arsenault et al., 2009).

*Rosa damascena*, commonly known as Damask rose, is known as GoleMohammadi in Iran. It is one of the most important species of Rosaceae family. Rosaceae are well-known or namental plants and have been referred to as the king of flowers (Nikbakht et al., 2004). At present time, over 200 rose species and more than 18000 cultivars form of the plant have been identified. Apart from the use of *R. damascena* as ornamental plants in parks, gardens, and houses, they are principally cultivated for using in perfume, medicine and food industry (Jabbarzadeh and Khosh-Khui, 2005).

*Rosa damascena* is traditionally used for treatment of abdominal and chest pains, strengthening the heart, menstrual bleeding, digestive problems and constipation. *R. damascena* has an important position in Iranian traditional medicine. It is economically a valuable plant with therapeutic applications in modern medicine. The antimicrobial, antioxidant, analgesic, anti-inflammatory, anti-diabetic and anti-depressant properties of R. damascena have been confirmed. Citronellol and geraniol as the main components of *R. damascena* essential oil are responsible for pharmacological activities (Mohaddese, 2016).

In traditional Medicines, the decoction of flowers was used for treatment of chest and abdominal pains, menstrual bleeding and digestive ailments (gentle laxative for constipation). It has been famous as
cardiotonic agent for strengthening the heart (Shahriari et al., 2006). Rose water traditionally was used as antiseptic agent for eye washing and mouth disinfecting and as antispasmodic agent for alleviating the abdominal pains, and bronchial and chest congestions (Akhmadieva et al., 1992).

The decoctions of dried rose water was used as diuretic and was recommended for relieving the fever, breast pain and menstrual problems. In Iranian traditional medicine, rose petals were cooked with sugar or honey and used for cooling the mind and body. Rose hips were prescribed as blood purifier and also are used by Iranian people with bread (Foster and Duke., 1990).

Thereupon, in the present investigation, the effect of rosa petals powder (rosa damascene) on blood lipids and glucose in experimental rats were studied.

2. Materials and Methods

Materials

*Rosa damascena* was purchased from the local market and Sheep’s tail fat were purchased from the local market in shebin EL-kom. Milted and blended it directly with experimental diet formulae and Alloxan were obtained from El-Gomhoriyac company, for trading Drugs, Chemicals or Medical instruments.

Biological Investigations

Animals: Fifty-Four Sprague – Dawley strain male albino rats, weighting 150 ±10 g per each were used in this study. All rats were fed the control basal diet for 7 consecutive days. Each rat was housed in an individual stainless steel cage under controlled condition. Diets were introduced to rats in a special non scattering feeding cup to avoid loss of food and contamination. Tap water was provided to rats by means of glass tubes projecting through wire cages from inverted bottles supported to one side of the cage.

Biological experiments

Basal diet

The basic diet prepared according to the following formula as mentioned by AIN, (1993) as follow: protein (12%), corn oil (10%), vitamin mixture (1%), salt mixture (4%), choline chloride (0.2%), methionine (0.3%), cellulose (5%) and the remained is corn starch (69.5%). The used vitamin mixture component was that recommended by
Campbell,(1963) while the salt mixture used formulated according to Hegsted,(1941).

**Induction of diabetes mellitus in rats**

Diabetes millets was induced in normal healthy male albino rats via intraperitoneal injection alloxan 125mg /kg body weight according to the method described by Desai and Bhide,(1985). Six hours after the injection of alloxan, fasting blood samples were obtained by retro-orbital method to estimate fasting serum glucose. Rats with a fasting blood glucose level above 200mg/dl were considered diabetic and were used in this study.

**Induction of hyperlipidemia in rats:**

Hyperlipidemia was induced by fed rats on diet containing high lipid (Basal diet +20% animal fat sheep's tail) for three consecutive weeks. Then, fasting blood serum obtained and TC, VLDL, LDL, HDL, and TG levels were estimated.

**Experimental design:**

Forty-five adult male albino rats, which fed on basal diet for one week. Then, divided into three main groups. All groups of rats were fed on the experimental diet for 30 days according to the following:

**First group:(5 rats)**

Rats fed on basal diet only

**Second group (diabetic rats):**

Diabetic rats were divided into four sub group (5 rats per each) according the following:

**Group 1:** Rats fed on basal diet as the positive control.

**Group 2:** Rats fed on basal diet containing 1% Rosa Petals powder (RPP).

**Group 3:** Rats fed on basal diet containing 2.5% RPP.

**Group 4:** Rats fed on basal diet containing 5% RPP.

**Third group (hyperlipidemic rats)**

Hyperlipidemic rats were divided into four sub group (5 rats per each) according the following:

**Group 1:** Rats fed on basal diet as the positive control

**Group 2:** Rats fed on basal diet containing 1% RPP.

**Group 3:** Rats fed on basal diet containing 2.5% RPP

**Group 4:** Rats fed on basal diet containing 5% RPP

**Blood sampling:** Blood samples were collected after 12 hour fasting at the end of the experiment. Using the retro – orbital method, by means of a microcapillary glass, Blood was collected into a dry clean centrifuge tube,
and left to clot in a water bath (37°C) at room temperature for half an hour. The blood was centrifuged for 10 minutes at 3000 r.p.m. to separate the serum. Serum was carefully aspirated and transferred into clean, dry plastic tubes and kept frozen at 20°C until analysis. The liver was removed and washed in saline solution, weighted in neutral buffered formalin solution (10%) according to methods described by Drury and Wallington (1980). Weight of organs was used to calculate the relative weight (%) in relation to total body weight.

**Biological Indices:** Biological evaluation of the different diets was carried out by determination of food intake (FI), body weight gain (BWG%) and feed efficiency ratio (FER) according to Chapman et al., (1959).

**Hematological analysis**

Different tested parameters in serum were determination using specific methods follow: Serum glucose according to Kaplan, (1984), Lipid cholesterol according to Allain, (1974), triglycerides (T.G) according to Fassati and Prencipe, (1982), high density lipoprotein (H.D.L-C) according to Lopez, (1977), low density lipoprotein (L.D.L-C) according to Lee and Nieman, (1996), Serum glutamate oxaloacetate transaminase S.GOT or (AST) according to Henry, (1974) and Young, (1975), S.GPT or (ALT) according to Young, (1975), serum alkaline phosphatase (ALP) according to IFCC, (1983).

**Histopathological Examination**

At the end of the experiment which continued for 30 successive days, all rats were sacrificed, tissue samples including liver was taken for histopathological examination according to Carleton, (1978).

**Statistical analysis**

Statistical analysis performed by using computer program statistical package for social science according to (SPSS, 1998).

**Results and discussion**

**Biological changes:**

Body weight gain (B.W.G%), Feed intake (F.I), and feed efficiency ratio (F.E.R) of diabetic and hyperlipidemic rats:

Table (1) showed B.W.G (%), (F.I) and (F.E.R). The mean value of body weight gain (B.W.G %) of negative control was significantly (p≤0.05) higher as compared with positive control, which was 71.67± 5.1 and 16.95±1.64% respectively. whereas the mean value of diabetic treated groups with 1%, 2.5% and 5% were 47.9±2.39, 57.32±2.72, and
58.62±1.13 % respectively. Whereas the mean value of diabetic treated groups (1%, 2.5% and 5%) were significantly high (p≤0.05) comparing with positive control. The best BWG% was for group 5% RPP. The same table illustrated that the mean value of (F.I) of diabetic treated groups fed on various diets. Results show that the mean value of (F.I) of control (+) group was lower than control (-) group it was being 14.7±0.85 and 22.25±0.85 (g/day/rat), respectively. Whereas the mean value of diabetic treated groups (1%, 2.5% and 5%) didn't show any significantly differences when compared with control (+). As for as, the mean value of (F.E.R) of diabetic treated groups fed on various diets. Data show that the mean value of (FER) of control (+) group was lower than control (-) group it was being 1.42±0.07 and 3.15±0.85, respectively, showing a significant difference. The mean value of FER of diabetic treated groups (1%, 2.5% and 5%) were significantly high (p≤0.05) comparing with positive control.

Hyperlipidemic treated groups with (1%, 2.5% and 5% rosa petals). As shown the mean value of body weight gain (B.W.G%) of negative control was significantly (p≤0.05) higher as compared with positive control, which was 71.67±5.1 and 39.07±0.48 % respectively. whereas the mean value of hyperlipidemic treated groups with 1% and 2.5% were 37.62±1.07 and 37.35±1.26 % respectively. didn't show any significant difference when compared with positive control. But, group 5% rosa petals was significantly less (p≤0.05) comparing with positive control. The same table illustrated that the mean value of F.I of negative control was higher significantly (p≤0.05) when compared with positive control, while all hyperlipidimic treated groups show a significant differences comparing with positive control.

As for as, the mean value of FER of control (-) group and All treated groups showed significantly lower when compared with control (+).

Biochemical changes:
- Effect of RPP on serum blood glucose of diabetic and hyperlipidemic rats.

- Table (2) result show the effect feeding on different levels of RPP on serum blood glucose . As shown in data the table , there were significant decreased in the level of blood glucose, after supplementation with 1, 2.5 and 5% RPP as compared with positive control group in the diabetic and hyperlipidemic rats. The best result was observed in the group fed on the basal diet containing 5% RPP .these results were in agreement with those reported by Gholamhoseiniana et al. (2009) who showed that rosa petals a dose of 2glkg body weight significantly decreased of blood glucose level in diabetic rats. The diet supplemented with dry rose petals had a decrease of glucose concentration of blood.

-Effect of different levels of RPP on serum lipid profile (mg/dL) of diabetic and hyperlipidemic rats:

Table (3) result show the effect feeding on different levels of RPP on serum lipid profile. As shown in the table, The levels of TC and TG were significant (P≤0.05) decreased after supplementation with RPP (1, 2.5 and 5%) as compared with positive control group in the diabetic and hyperlipidemic rats. Incase of HDL level for diabetic and hyperlipidemic rats after supplemented with RPP (1%, 2.5 and 5%) as compared with positive control group. However, the level of LDL and VLDL were significant (P≤0.05) decreased. Numerically, the best serum TC, TG, HDL, LDL and VLDL was recorded for group 5% RPP when compared to control (-) group. these results were in agreement with those reported by Gholamhoseinian et al., (2012) found that (Rosa damascene) effects on reduction of total cholesterol, triglyceride and low density lipoprotein and plaques formation. It has no effect on high density lipoproteins levels. Therefore, the anti hyperlipidemic effects of R. damascena methanol extract is caused through inhibiting the activities of pancreatic lipase and HMG COA reductase.
